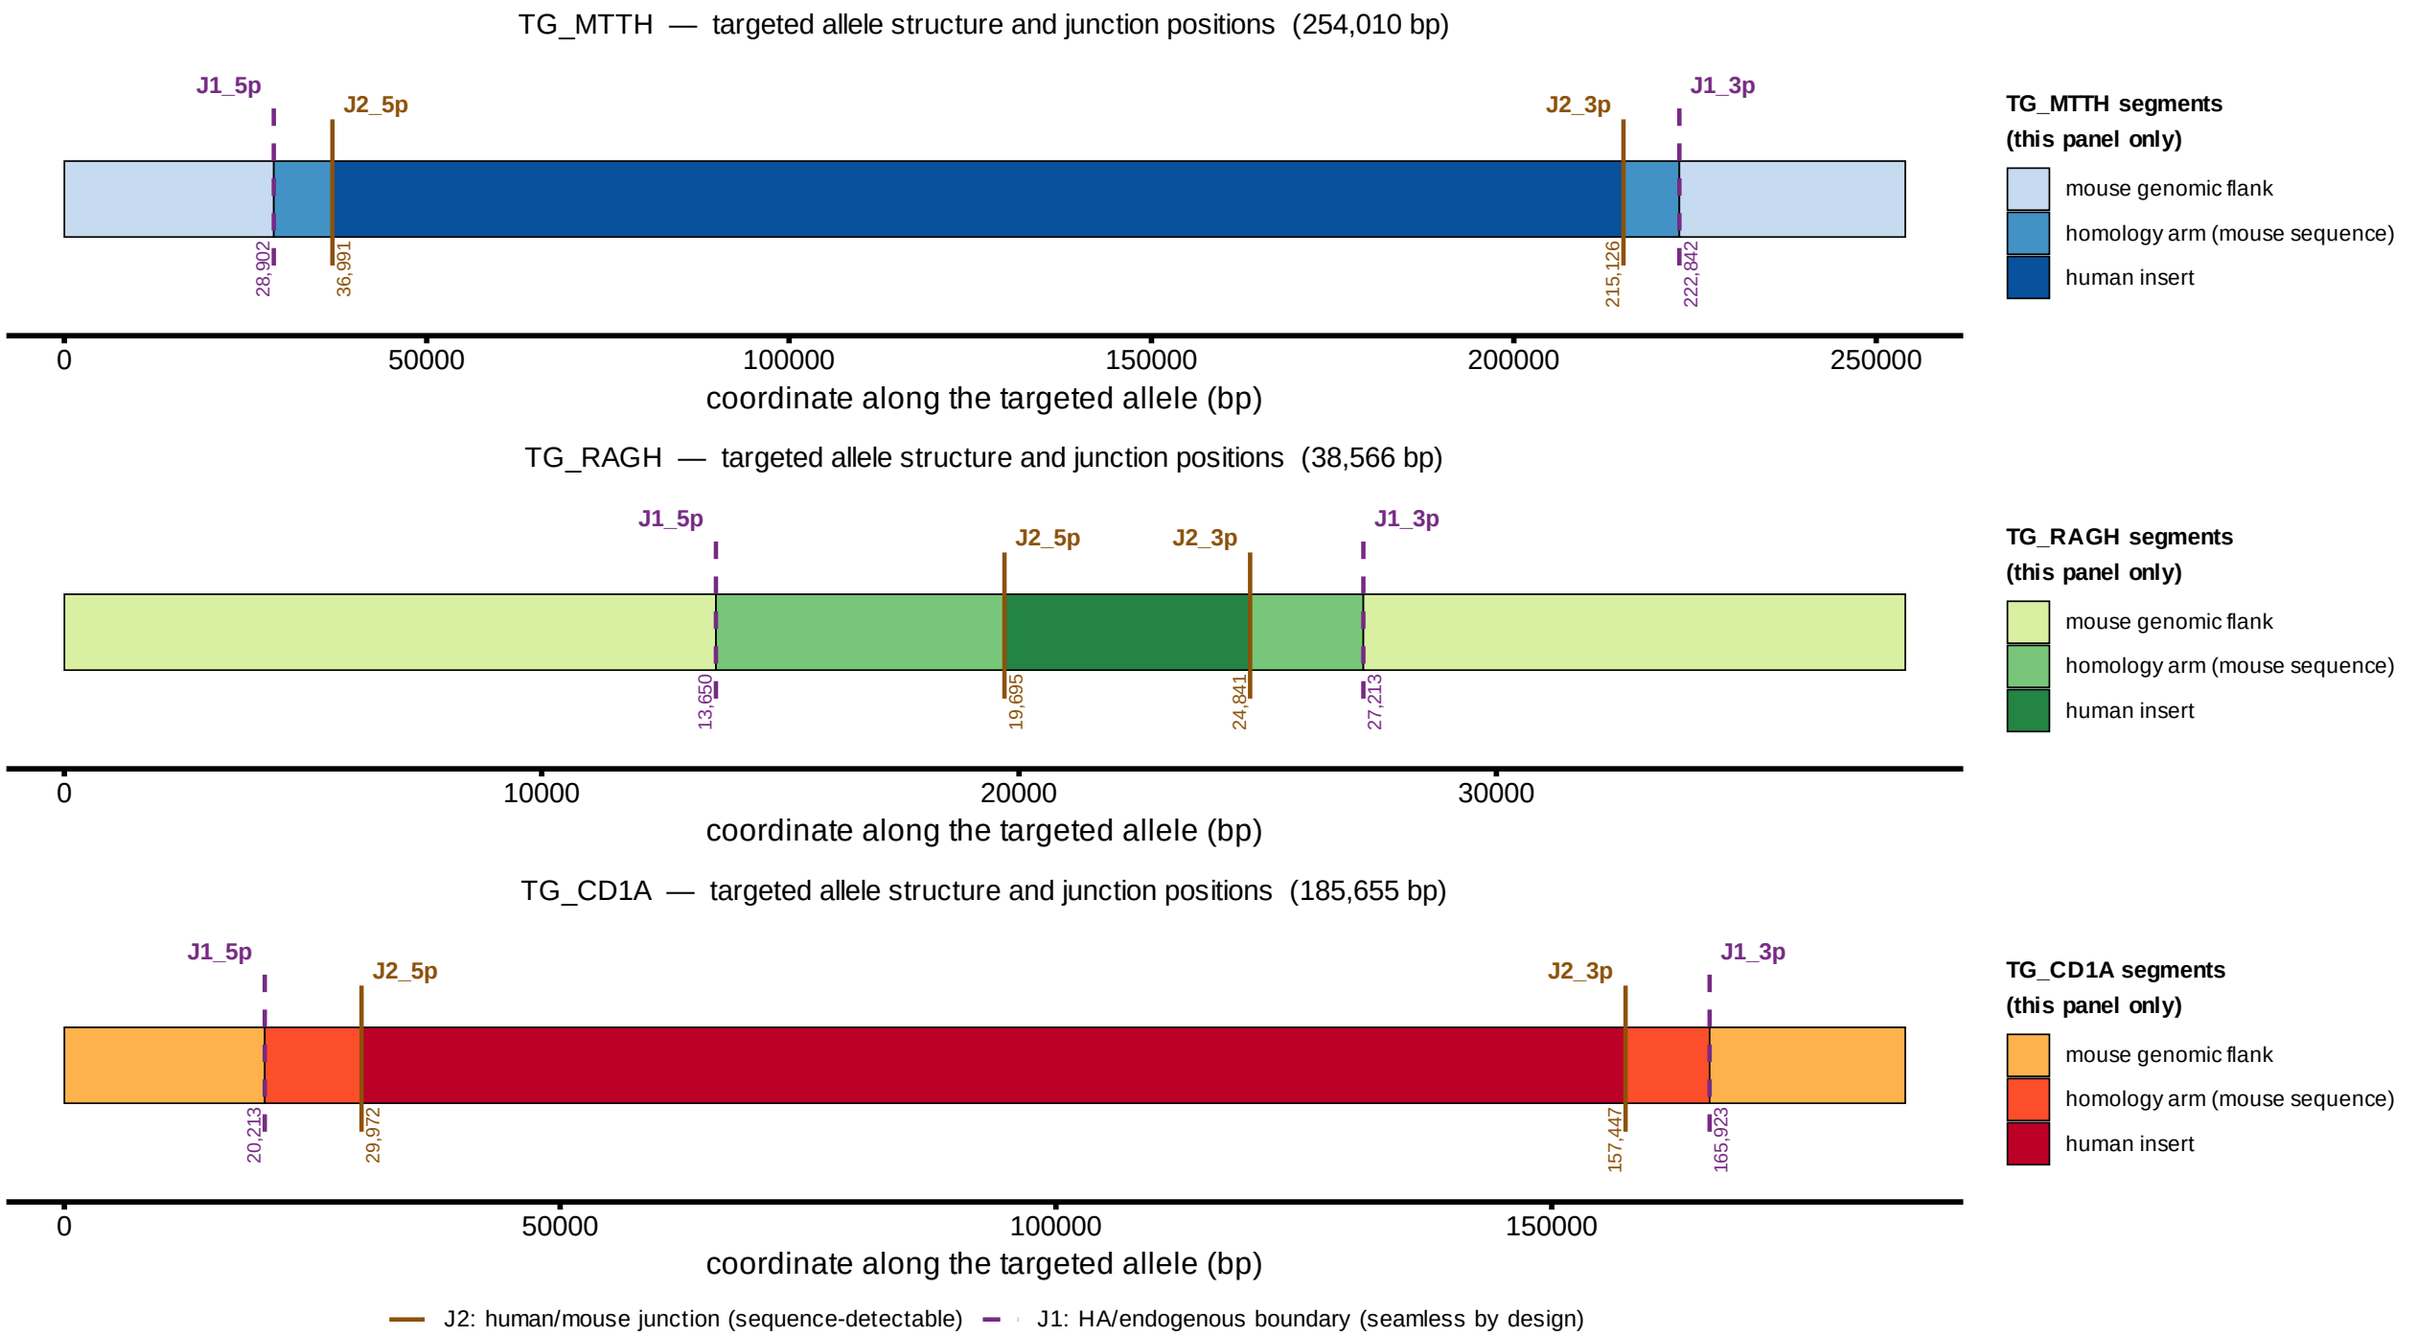
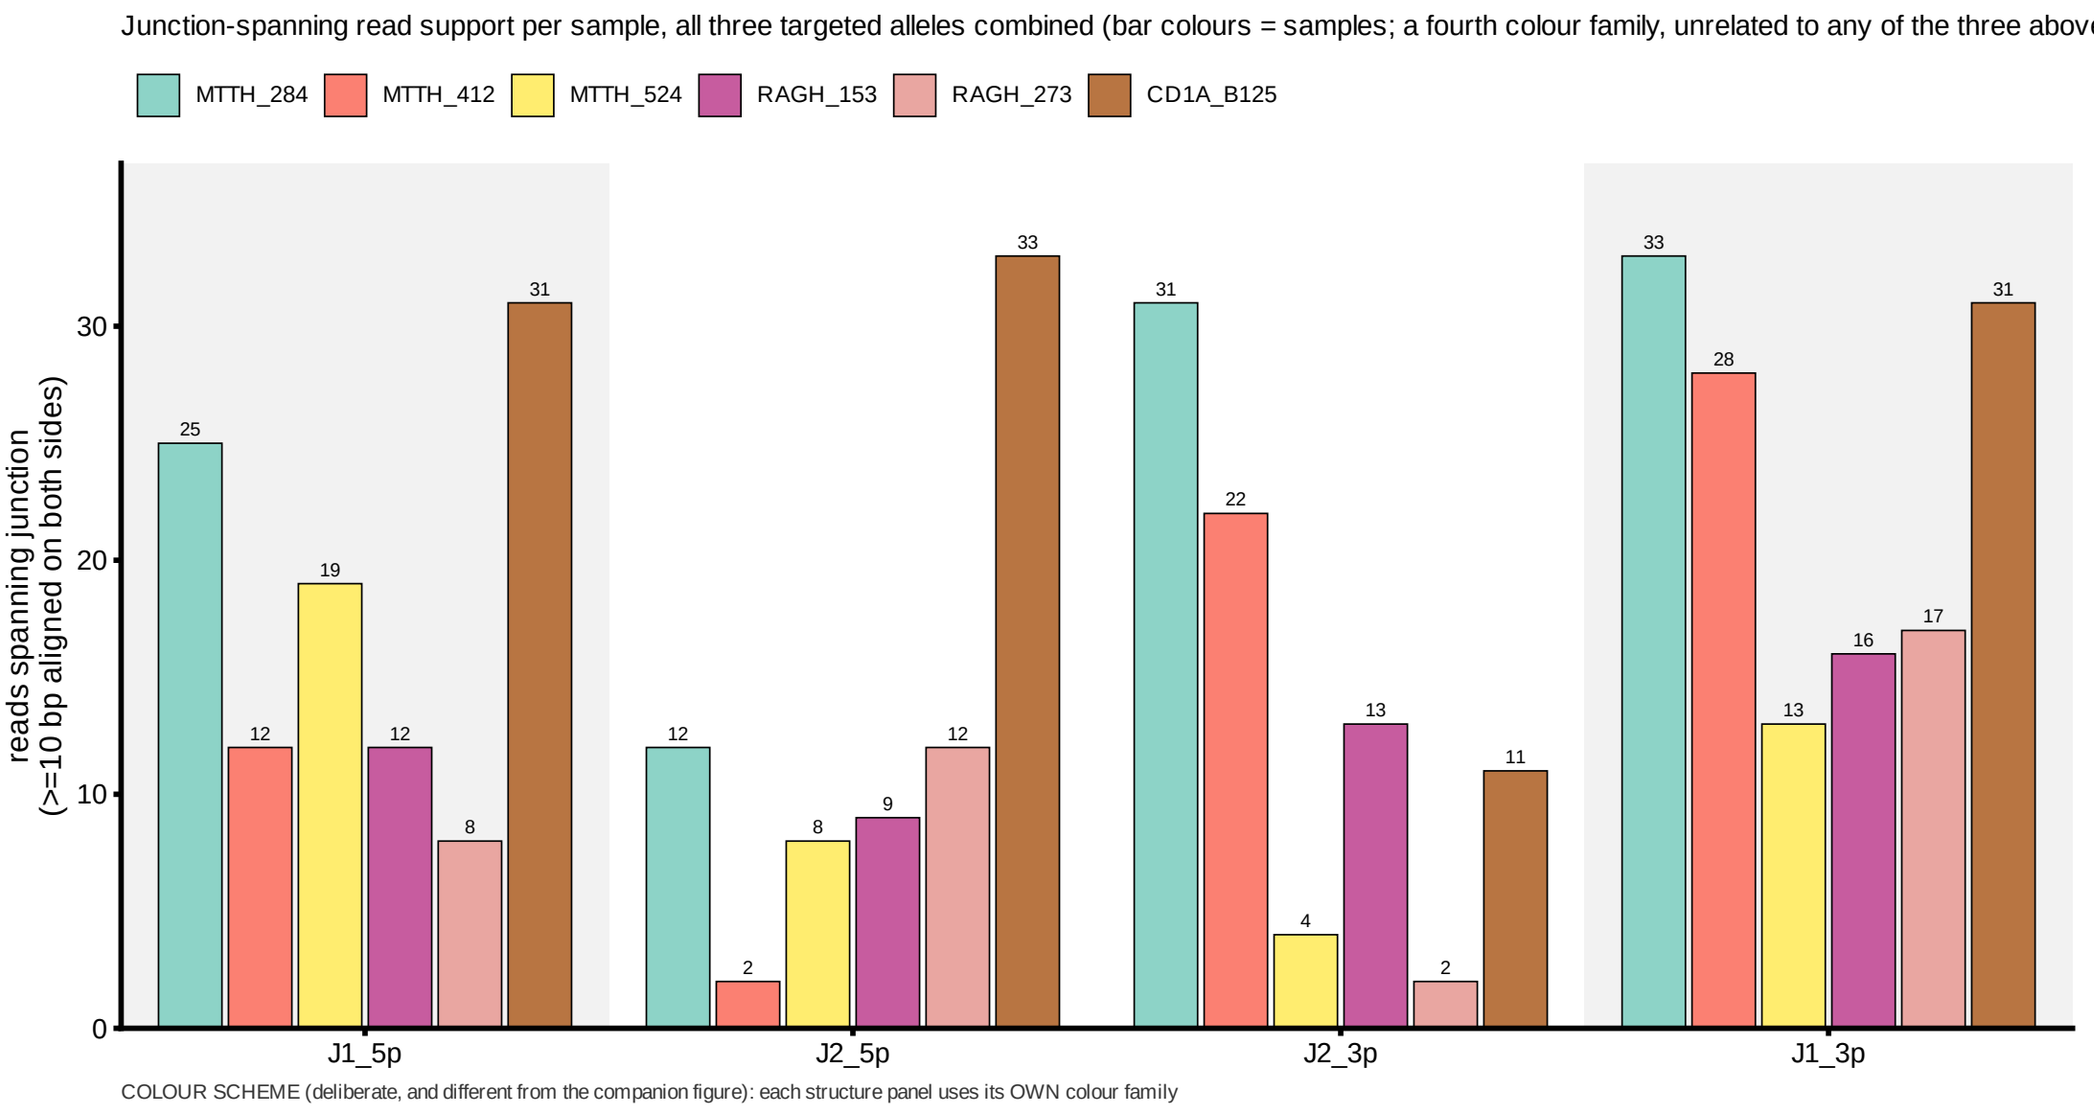
Three targeted alleles, one colour family each — structure (top) and junction-spanning read support (bottom)



Junction-spanning read support per sample, all three targeted alleles combined (bar colours = samples; a fourth colour family, unrelated to any of the three above)



COLOUR SCHEME (deliberate, and different from the companion figure): each structure panel uses its OWN colour family — TG_MTTH blue, TG_RAGH yellow-green, TG_CD1A orange-red. Within every family the order is fixed: light = mouse flank, mid = homology arm, dark = human insert. Read each panel against ITS OWN legend; colours are NOT comparable between panels. Bar colours in the bottom panel are samples and are unrelated to all of the segment colours above.

The four bar groups are junction CLASSES, not one shared coordinate: each sample carries its own targeted allele, so counts are compared within a class, never between loci. The three structure panels are drawn on INDEPENDENT x scales (254,010 / 38,566 / 185,655 bp) and their widths are therefore not comparable.

Shaded groups (J1): the homology arm is identical to the endogenous locus, so these reads cannot be assigned to one or the other — the aligner splits them arbitrarily and reports MAPQ 0. J1 counts are therefore NOT a measure of evidence strength and are not comparable with J2 counts. Only J2 reads (MAPQ 60) uniquely identify the targeted allele.
