
Bar colours = samples. The four groups are junction CLASSES, not one shared coordinate: each sample carries its own targeted allele (TG_MTTH / TG_RAGH / TG_CD1A), so counts are compared within a class, never between loci.

Shaded groups (J1): the homology arm is identical to the endogenous locus, so these reads cannot be assigned to one or the other — the aligner splits them arbitrarily and reports MAPQ 0. J1 counts are therefore NOT a measure of evidence strength and are not comparable with J2 counts. Only J2 reads (MAPQ 60) uniquely identify the targeted allele.
